Design Iteration Log (300-400 words):

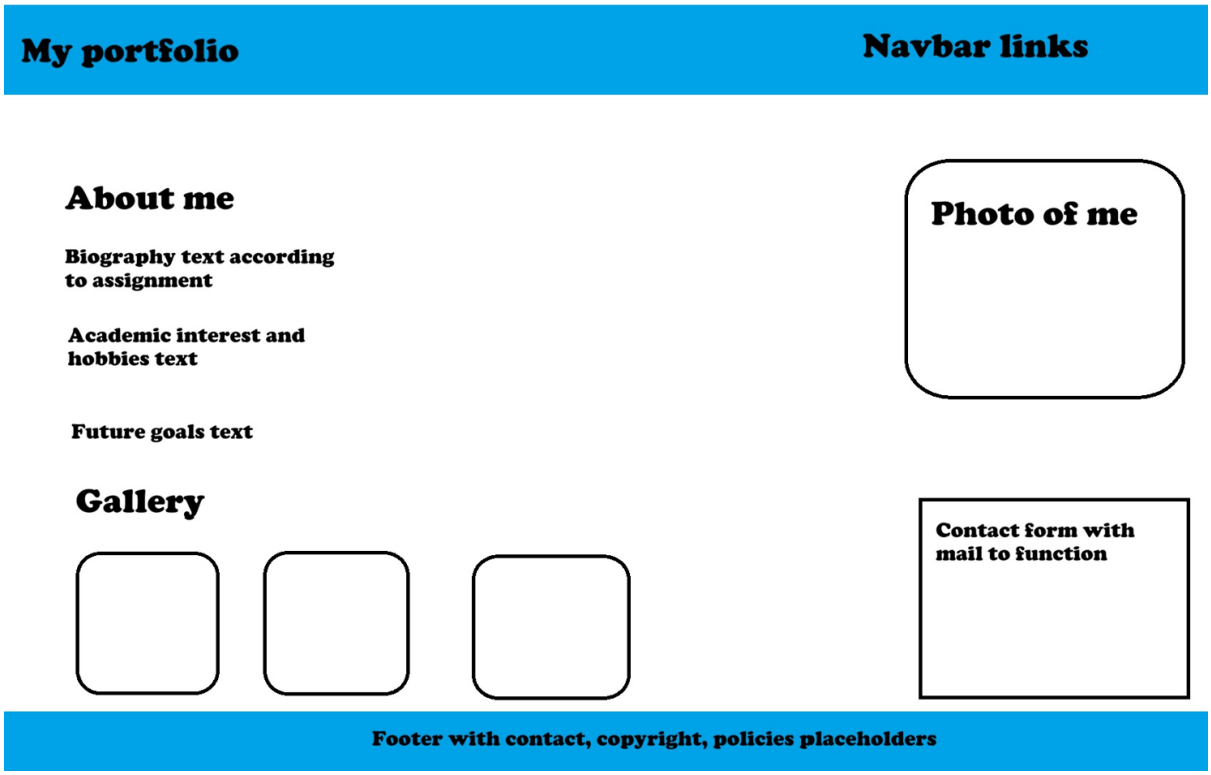

- Describe your initial design idea

My initial design idea was to create a fairly basic portfolio page with clear sections where the user will get a good overview of the whole web page as soon as its opened. The color and font choices are focused on the site being clear and easy to read with good font size, text and background colors. I like to have the header and footer in the same colorway as that also creates clear boundaries for the main section of the page. I think it looks good and seems to be quite used on other popular web pages. The gallery images should be large enough so the user can see the pictures clearly while not taking up most of the space on the web page. I also wanted the contact form to be easy to reach and fill in. That meant clear labels and input fields with correct sizing.

- Show/describe at least TWO changes you made and why

In my draft design I was thinking about the possibility to show the entire web page on the screen, without the need to scroll down. I changed that to the web page taking up plenty more space vertically because the page would be way too compact, not giving each section and images enough room. I also wanted the navigation links to show the functionality by smoothly scrolling down to each section when clicking the link (e.g. about me). Another change I made was to move my profile picture from the gallery section to about me to complement the biography section as it looked unfinished with just text. The photo made it look more professional in my opinion. With that change made I also added another image to the gallery so there are three images side to side.

- Include a hand-drawn sketch or screenshot of your first attempt

This was my design idea. It did look ok in theory but in practice everything could not fit with the page still being easy to read and presented in a good way. Many of the sections and elements ended up needing a lot more space than in my initial draft.

Technical Challenges Section:

- List 3 specific problems you encountered

1. The sizing and styling of the photos was initially difficult as they were so large and took up way too much of the web page. Re-sizing and keeping the correct ratio were something I had to work with.

2. The usage of "&" was something I also got a small problem with as the character is not valid inside HTML text.

3. The display of my biography section on smaller screens (<768px). The image would appear squeezed.

- Explain how you solved each one

1. For the profile picture I assigned it a fixed max-width (300px) and height (300px). Object-fit: cover so the photo was cropped correctly. Border-radius: 50% so its circular. Gallery images assigned max-width: 350px and width: 100%, height: auto so the images also scale.

2. Researched and found "&amp" which I used like this:
<h3>Academic interest & Hobbies</h3>

3. Change in @media to flex-direction: column (instead of flex) and also gave the image fixed size of max-width: 200px, height: 200px.

- Include relevant code snippets with comments

```
/* Profile picture in biography styling */
.bio img {
  flex: 1;
  max-width: 300px;
  height: 300px;
  object-fit: cover;
  border-radius: 50%;
  box-shadow: 0 4px 8px rgba(0, 0, 0, 0.1);
}
```

Styling for my profile picture for it to be presented with correct ratio, size and circular.

```
<h3>Academic interest &amp;amp; Hobbies</h3>
```

```
<li>Football &amp;amp; Sports</li>
<li>Travel &amp;amp; Culture</li>
<li>Health &amp;amp; Fitness</li>
```

Using “&” instead of only “&” solved this issue.

```
.bio {
  flex-direction: column;
  text-align: center;
}

.bio img {
  max-width: 200px;
  height: 200px;
}
```

Flex-direction: column instead of flex and a smaller fixed width and height. This is for smaller screens (<768px) in @media.

Personal Reflection:

- What surprised you most about this assignment?

Even though at first glance it would appear to be a straight forward assignment I found myself spending a lot of time on small details, color choices and styling. There can be much to add for the web page to go from basic to more professional looking.

- Which CSS property gave you the most trouble and why?

Flex-direction because of the placement of the different elements. especially for the @media section, as I used “flex” throughout my web page which did not work as intended on smaller screens.

- How did your final design differ from what you originally imagined?

The web page design finally grew to be much larger than my initial design, which I am happy with as it now looks clearer with each section having their own space to be presented in. Even though there are no section borders etc. you can see a clear distinction from the different contents on the web page.
